# Customer needs

- ∅ The plant is made by a ring (80m long) along which there are 21 trolleys
- ∅ Each trolley has 2 Control Technique drives (DP slaves) and should move independently from the others
- ∅ Two trolleys cannot be closer than 5 cm.
- ∅ The complete system should be controlled by a single CPU, without any kind of intelligence on trolleys

## Customer needs (2)

- Ø In the past the customer has used a PROFIBUS solution based on sliding contacts
- Ø System performance were enough only for a little number of trolley
- Ø Customer want to have at least:
  - Ø IO Update rate  $\leq 64\text{ms}$
  - Ø Quantity of data to exchange with each trolley: 128 bytes

Solution:

PROFINET IO implemented  
on a Wireless LAN network

# Solution system architecture

WLAN vs. determinism

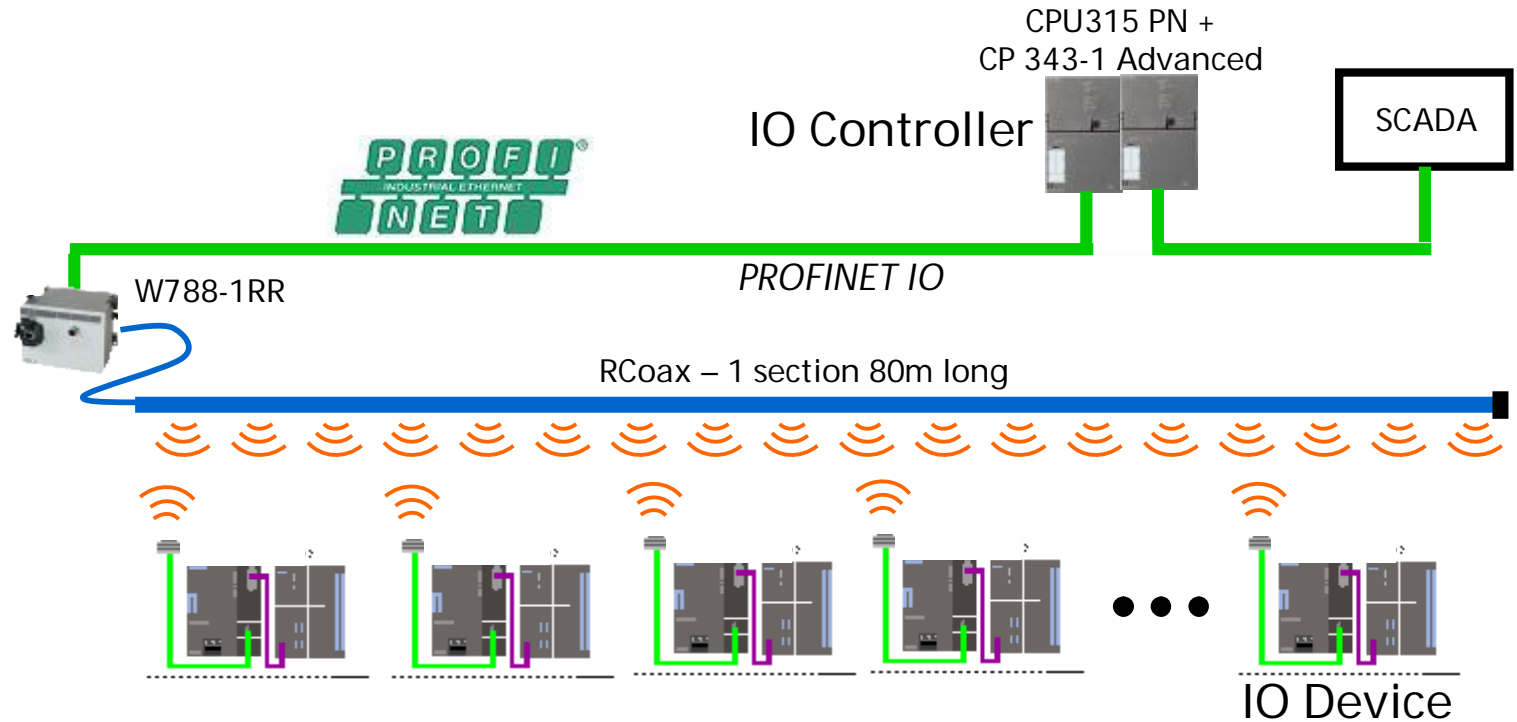

Roaming in industrial application

RCoax cable

Practical implementation

Results

**SIEMENS**

- Ø SCALANCE W788 RR as access point with iPCF function
- Ø Rcoax cable as antenna all around the ring
- Ø 21 trolleys, each one with:
  - Ø IWLAN/PB Link PN IO as proxy between PROFINET IO and PROFIBUS DP
  - Ø 2 non Siemens PROFIBUS DP slave

# WLAN vs. determinism

WFCS 2006

Customer needs

WLAN vs.  
determinism

Roaming in industrial  
application

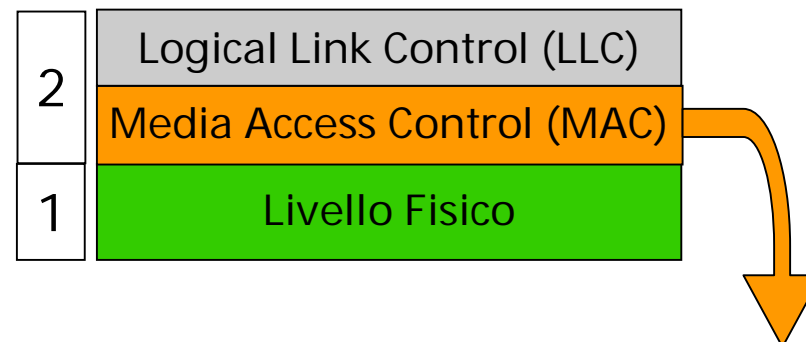

RCoax cable

Practical  
implementation

Results

**SIEMENS**

- ∅ WLAN is based on a shared and poor medium
- ∅ The access control is typically based on CSMA; in a certain time only one client can transmit
- ∅ When a high number of collision happened the network performance could be very low

DCF (Distributed Coordinated Function) à CSMA/CA

PCF (Point Coordinated Function) à Polling

# The 802.11 protocol

WFCS 2006

Customer needs

WLAN vs.  
determinism

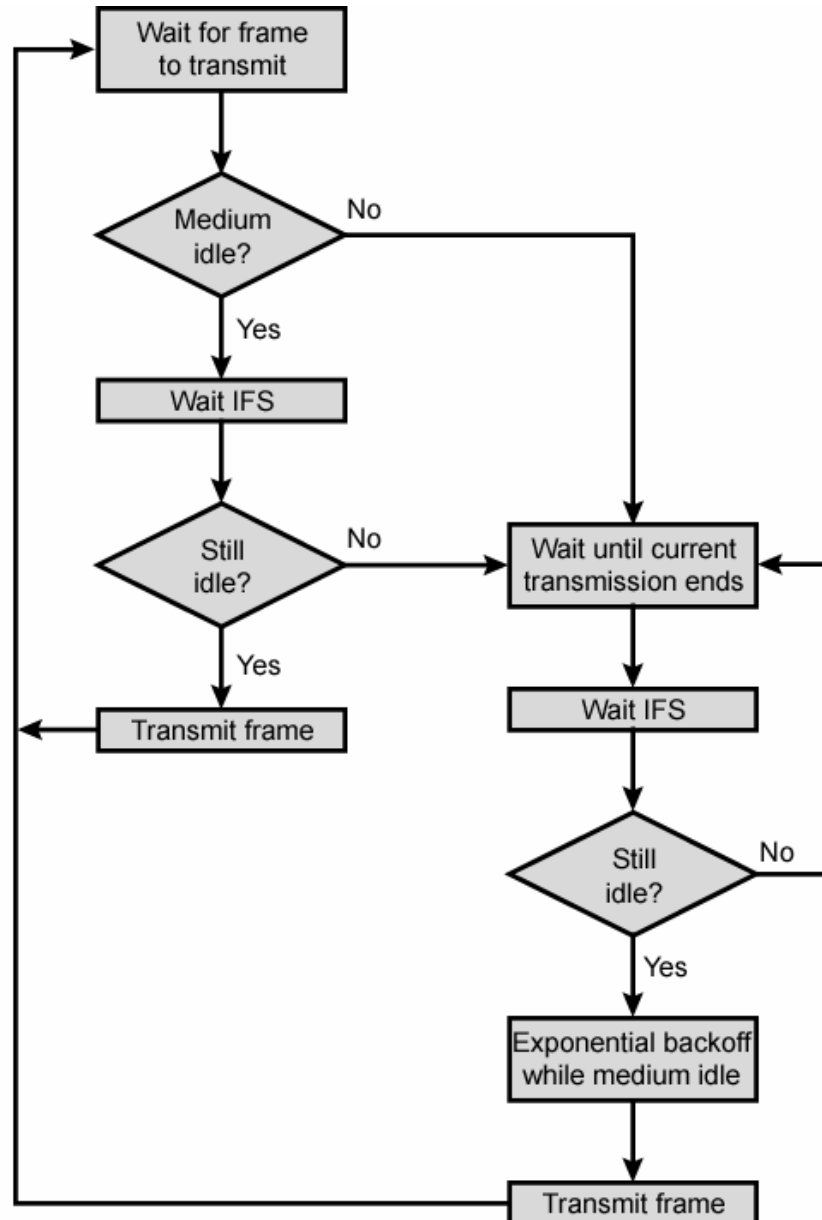

Roaming in industrial  
application

RCoax cable

Practical  
implementation

Results

**SIEMENS**

Ø Each client waits the medium idle for at least a time = IFS

Ø If the medium is still idle, the client waits until the current transmission ends and, after IFS, start an exponential backoff

Ø Collisions could be avoided by RTS/CTS technique (Collision Avoidance)

IFS: Inter Frame Space

# Contention free services: Point Coordination Function (PCF)

WFCS 2006

Customer needs

WLAN vs.  
determinism

Roaming in industrial  
application

RCoax cable

Practical  
implementation

Results

**SIEMENS**

∅ PCF is implemented above the DCF

∅ The critical traffic is managed by the access point simply using a polling technique scheduled by a round robin algorithm

∅ The rest of the traffic share the medium with CSMA/CA

∅ Each time slot is divided into 2 periods; the first in which PCF is applied and the second one in which DCF is used

# PCF implementation

WFCS 2006

Customer needs

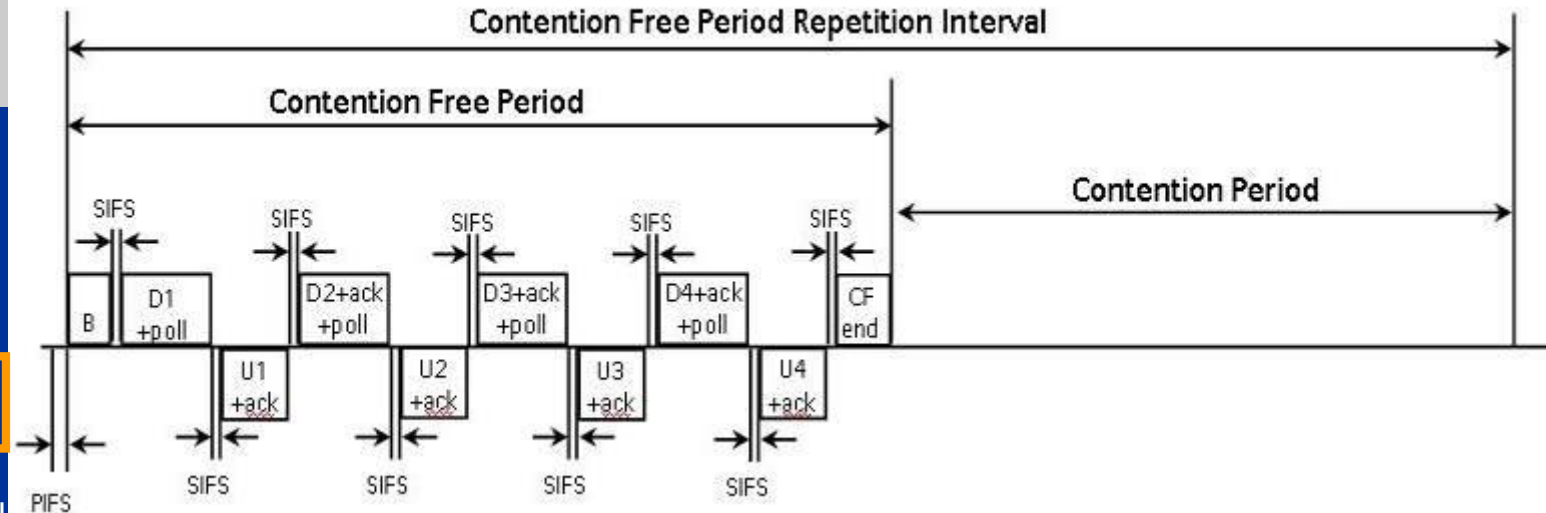

WLAN vs. determinism

Roaming in industrial application

RCoax cable

Practical implementation

Results

∅ The use of a mixed solution (PCF and DCF) can lead to a high jitter between a Contention Free Period Repetition Interval and the next one

∅ In order to have controlled jitter it could be used a solution based on a pure PCF

↳ **iPCF = Industrial + PCF**

# The roaming time in industrial applications

- Ø The roaming mechanism is not defined into the 802.11 standard
- Ø Inside the standard are explained some topics related to roaming:
  - Ø Scanning (active / passive)
  - Ø Association
  - Ø Authentication
- Ø Roaming time is obtained by adding this 3 times and it's not easy to estimate
- Ø Some of these times could be reduced:
  - Ø Scanning on fixed and specified channels
  - Ø Use simple security techniques (such as WEP) in order to reduce authentication time

# Roaming times: some examples

WFCS 2006

- ∅ Scan on defined channels
- ∅ iPCF functionality
- ∅ Security based only on WEP

Roaming time  $\leq 50\text{ms}$

RCoax cable

Practical  
implementation

Results

**SIEMENS**

- Ø Used as antenna connected to SCALANCE W
- Ø Optimal and stable coverage in the proximity of the cable
- Ø No interferences to/from other Wi-Fi networks
- Ø Two different versions for 2.4GHz and 5GHz
- Ø Easy to install thanks to his flexibility

Results

**SIEMENS**

- Ø We started with IEEE 802.11b (DCF) because the distance between client antenna and RCoax cable was not too high
- Ø Signal strength on the each client was quite good but very “unstable”, there were a lot of data rate changing
- Ø The high number of clients and this signal situation leded to a high traffic volume and a lot of transmission errors
- Ø Sometimes some trolleys lost the connection with the PLC IO Controller

We decided to activate iPCF functionality with a fixed data rate at 5.5 Mbit/s

# Signal strength on a client

Roaming in industrial  
application

RCoax cable

Practical  
implementation

Results

- Ø The system has been working properly since last November
- Ø The PROFINET IO update rate is 64ms with 128 bytes exchanged with each trolley on each CPU cycle
- Ø The customer is satisfied with this solution and is going to install a twin plant just beside this one

**PROFINET IO could be implemented also on WLAN network with good results!**
